

# Estimating Surface Normals in Noisy Point Cloud Data

Niloy J. Mitra, An Nguyen, Leonidas Guibas

## Abstract

We analyze a method based on local least square fitting for estimating the normals at all the sample points of a point cloud data (PCD) set, in the presence of random noise. We study the effects of neighborhood size, curvature, sampling density, and noise on the normal estimation when the PCD is sampled from a smooth curve in 2D or a smooth surface in 3D and noise is added.

## The Normal Estimation Problem

### Given

A noisy point cloud data (PCD) sampled from a surface (or curve) without any connectivity information

### Goal

Compute surface normals at each point  $p$

## Related work

### Voronoi-diagram based approach

- Do a surface reconstruction (Crust, Cocone)
- Compute normals from the reconstructed surface
- Works in *absence* of noise

### Surface fitting

- As found in works of Hoppe, Pauly, Alexa
- Pointshop3D, Progressive Point Set
- Use least square fit to a neighborhood of radius  $r$  around point  $p$
- Works in *presence* of noise
- Neighborhood size picked *manually*

## Normal Estimation using Plane Fitting

## Contributions

- Study the effects of curvature, noise, sampling density on the choice of neighborhood size
- Use this insight to choose an optimal neighborhood size
- Compute bound on the estimation error

## Least Square Fit

- Assume best fit surface:  $a^T p = c$

- Minimize  $\frac{1}{k} \sum_{i=1}^k (a^T p_i - c)^2$

- Reduce to an eigenvalue problem

$$M = \frac{1}{k} \sum_{i=1}^k (p_i - \bar{p})(p_i - \bar{p})^T$$

- Smallest eigenvector of  $M$  is our estimate of the normal to the surface

### Collusive Noise

### Curvature Effect

## Two Extremes of Deception

## Analysis

- Assume,  $k$  points are uniformly distributed with density  $\rho$  within a ball of radius  $r$
- Noise
  - independent of measurement
  - zero mean, known variance  $\sigma_n$
- From the *evenly distributed* sample assumption
  - Bound all entries of the covariance matrix  $M$
  - Important fact: Summation tends to expectation as the number of samples increases
  - Get a bound on the estimation error

## Result in 2D

$$\text{error} \leq c_1 \kappa r + c_2 \frac{\sigma_n}{\sqrt{\epsilon \rho r^3}} + c_3 \frac{\sigma_n^2}{r^2}$$

result holds with probability  $1-\epsilon$

- This suggests, to minimize error when density is
  - high, choose optimal  $r$  as  $c (\sigma_n^2 / \kappa)^{1/3}$
  - low, choose optimal  $r$  as  $c (\sigma_n^2 / (\epsilon \rho \kappa^2))^{1/5}$
- For flat surface,  $\kappa=0$ , can make error arbitrarily small
- For no noise,  $\sigma_n=0$ , pick as small a neighborhood as possible

## 2D: Simulation and Prediction

$$\text{error} \leq c_1 \kappa r + c_2 \frac{\sigma_n}{\sqrt{\epsilon \rho r^3}} + c_3 \frac{\sigma_n^2}{r^2}$$

## Result in 3D

- A more involved but similar analysis in 3D gives the following bound

$$\text{error} \leq \theta(1) \kappa r + \theta(1) \sigma_n / (r^2 \sqrt{\epsilon \rho}) + \theta(1) \sigma_n^2 / r^2$$

- So a good choice of  $r$  is given by

$$r = \left( \frac{1}{\kappa} \left( c_1 \frac{\sigma_n}{\sqrt{\epsilon \rho}} + c_3 \sigma_n^2 \right) \right)^{1/3}$$

## Exact Model used to Choose $c_1, c_2$

## Estimation Error > 5°

## Effects of Curvature, Noise on Neighborhood Size

## Effect of Increasing Noise on Estimation Error

## Algorithm for Normal Estimation in 3D

- Choose  $c_1, c_2$
- Initialize  $k=15$
- Iterate and refine (10 steps or less)
  - Compute  $r, \rho, \kappa$  locally
    - $r \approx$  distance to  $k$ -th nearest neighbor
    - $\rho = k / \pi r^2$
    - $\kappa$  computed using Gumhold's method
  - Use  $\rho, \kappa$  to estimate  $r_{new}$
  - Re-estimate  $k_{new} = \pi r_{new}^2 \rho_{old}$
- Stop if
  - $k$  threshold or,
  - $k$  saturates
- Use least square fit on the  $k$ -nearest neighbors to get the normal estimate to the surface at  $p$
